

A non-empty zero-indexed array A consisting of N integers is given. Array A represents numbers on a tape. Any integer P, such that  $0 < P < N$ , splits this tape into two non-empty parts: A[0], A[1], ..., A[P - 1] and A[P], A[P + 1], ..., A[N - 1].

The *difference* between the two parts is the value of:  $|(A[0] + A[1] + \dots + A[P - 1]) - (A[P] + A[P + 1] + \dots + A[N - 1])|$ . In other words, it is the absolute difference between the sum of the first part and the sum of the second part.

For example, consider array A such that:

```
A[0] = 3
A[1] = 1
A[2] = 2
A[3] = 4
A[4] = 3
```

We can split this tape in four places:

- P = 1, difference =  $|3 - 10| = 7$
- P = 2, difference =  $|4 - 9| = 5$
- P = 3, difference =  $|6 - 7| = 1$
- P = 4, difference =  $|10 - 3| = 7$

Write a function:

```
int solution(vector<int> &A);
```

that, given a non-empty zero-indexed array A of N integers, returns the minimal difference that can be achieved. For example, given:

```
A[0] = 3
A[1] = 1
A[2] = 2
A[3] = 4
A[4] = 3
```

the function should return 1, as explained above.

Assume that:

- N is an integer within the range [2..100,000];
- each element of array A is an integer within the range [-1,000..1,000].

Complexity:

- expected worst-case time complexity is  $O(N)$ ;
- expected worst-case space complexity is  $O(N)$ , beyond input storage (not counting the storage required for input arguments).

Elements of input arrays can be modified.
